## K-Mean Clustering and Hierarchical Clustering

	K-mean Clustering	Hierarchical Clustering
Key operation	Aims to partition n observations into k clusters in which each observation belongs to the cluster with the nearest mean	Repeatedly combine two nearest clusters  Centroid: the average of all data points in the cluster  Clustroid: an existing data point that is closest to all other points in the cluster
Operation chart	Step 1 Step 2 Step 3 Step 5 Step 6	Dendrogram  C  E  Dendrogram  A  B  C  E  A  B  C  D  A  B  C  D  E  F
Comparison	<ul> <li>time complexity</li> <li>produces a single partitioning</li> <li>need K – number of clusters to be specified</li> <li>starts with a random choice of cluster centers, therefore it may yield different clustering results on different runs of the algorithm</li> </ul>	<ul> <li>can be slow</li> <li>give different partitioning depending on the level of resolution</li> <li>doesn't need number of clusters to be specified</li> <li>reproductable, can get the same clustering result on different runs</li> <li>cannot handle big data</li> </ul>
